1 Introduction

The task is to design a data structure to answer 2D orthogonal range reporting queries efficiently. Given a static set P of n points in \mathbb{R}^2 , we wish to preprocess the points such that for a given axis-aligned query rectangle Q , all points inside Q can be reported quickly.

Two implementations are developed:

- (a) A standard 2D Range Tree without optimizations.
- (b) A 2D Range Tree with **Fractional Cascading** to speed up queries.

We compare the time complexities theoretically and empirically by running experiments on random point sets of various sizes.

2 Problem 1: Standard 2D Range Tree

2.1 Pseudocode

Algorithm 1 Build 2D Range Tree

```
1: procedure BUILDXTREE(points)
2:   if points is empty then
3:     return None
4:   end if
5:   Sort points by x-coordinate
6:   mid  $\leftarrow$  median point
7:   node  $\leftarrow$  new Node with mid point
8:   node.left  $\leftarrow$  BuildXTree(points left of mid)
9:   node.right  $\leftarrow$  BuildXTree(points right of mid)
10:  return node
11: end procedure
```

Algorithm 2 Build Y-Tree

```
1: procedure BUILDYTREE(points)
2:   if points is empty then
3:     return None
4:   end if
5:   Sort points by y-coordinate
6:   mid  $\leftarrow$  median point
7:   node  $\leftarrow$  new Node with mid point
8:   node.left  $\leftarrow$  BuildYTree(points left of mid)
9:   node.right  $\leftarrow$  BuildYTree(points right of mid)
10:  return node
11: end procedure
```

2.2 Querying Pseudocode

2.3 Approach and Time Complexity

Approach:

- Build a primary BST on *x*-coordinates.

Algorithm 3 Build Full 2D Range Tree

```
1: procedure BUILD2DRANGETREE( $XTreeRoot, points$ )
2:   if  $XTreeRoot$  is None then
3:     return None
4:   end if
5:    $node \leftarrow$  new Node
6:    $node.point \leftarrow XTreeRoot.point$ 
7:    $node.associatedStructure \leftarrow$  BuildYTree( $points$ )
8:   Partition  $points$  into  $leftPoints$  and  $rightPoints$  by  $x$ -coordinate
9:    $node.left \leftarrow$  Build2DRangeTree( $XTreeRoot.left, leftPoints$ )
10:   $node.right \leftarrow$  Build2DRangeTree( $XTreeRoot.right, rightPoints$ )
11:  return  $node$ 
12: end procedure
```

Algorithm 4 Query 2D Range Tree

```
1: procedure QUERY( $xmin, xmax, ymin, ymax$ )
2:    $splitNode \leftarrow$  find node where  $x$  splits
3:   if  $splitNode$  is None then
4:     return empty set
5:   end if
6:   Initialize  $result \leftarrow \emptyset$ 
7:   Search left and right subtrees:
8:     Collect points within  $[ymin, ymax]$  from associated  $Y$ -trees
9:     Only visit subtrees where  $x$ -ranges intersect  $[xmin, xmax]$ 
10:  return  $result$ 
11: end procedure
```

- At each node, build a secondary BST (Y-tree) on y -coordinates for all points in the subtree.
- For a query, find the split node and explore only relevant subtrees.

Complexities:

- Preprocessing Time: $\mathcal{O}(n \log n)$
- Query Time: $\mathcal{O}(\log^2 n + k)$ where k = number of output points

3 Problem 2: 2D Range Tree with Fractional Cascading

3.1 Pseudocode

Algorithm 5 Build 2D Range Tree with Fractional Cascading

```
1: procedure BUILDYLIST(points, leftPoints, rightPoints)
2:   Initialize out  $\leftarrow$  empty list
3:   Maintain two pointers leftPtr, rightPtr for left and right children
4:   for each point p in points sorted by y do
5:     Record leftPtr and rightPtr positions (or  $-1$  if none)
6:     Append [p, leftPtr, rightPtr] to out
7:     if p matches leftPoints[leftPtr] then
8:       leftPtr  $\leftarrow$  leftPtr + 1
9:     end if
10:    if p matches rightPoints[rightPtr] then
11:      rightPtr  $\leftarrow$  rightPtr + 1
12:    end if
13:  end for
14:  return out
15: end procedure
```

Algorithm 6 Query 2D Range Tree with Fractional Cascading

```
1: procedure QUERY(xmin, xmax, ymin, ymax)
2:   Find split node
3:   Use binary search to locate starting index in associated Y-list
4:   Follow precomputed pointers efficiently without repeated searches
5:   Collect points within the y-range, prune unnecessary branches
6:   return result points
7: end procedure
```

3.2 Approach and Time Complexity

Approach:

- Similar to the normal 2D Range Tree.

- Instead of full Y-trees, store sorted Y-lists with cross-references (pointers) between parent and child Y-lists.
- Perform only a single binary search at the split node and use pointers thereafter.

Complexities:

- Preprocessing Time: $\mathcal{O}(n \log n)$
- Query Time: $\mathcal{O}(\log n + k)$ where k = number of output points

4 Comparison Between Standard and Fractional Cascading Range Trees

4.1 Experimental Setup

For experiments:

- Random points in the range $[-100, 100]^2$ were generated for different n .
- Random query rectangles were used.
- Measured both preprocessing time and query time.
- Verified that the outputs of both methods match.

4.2 Description of Results

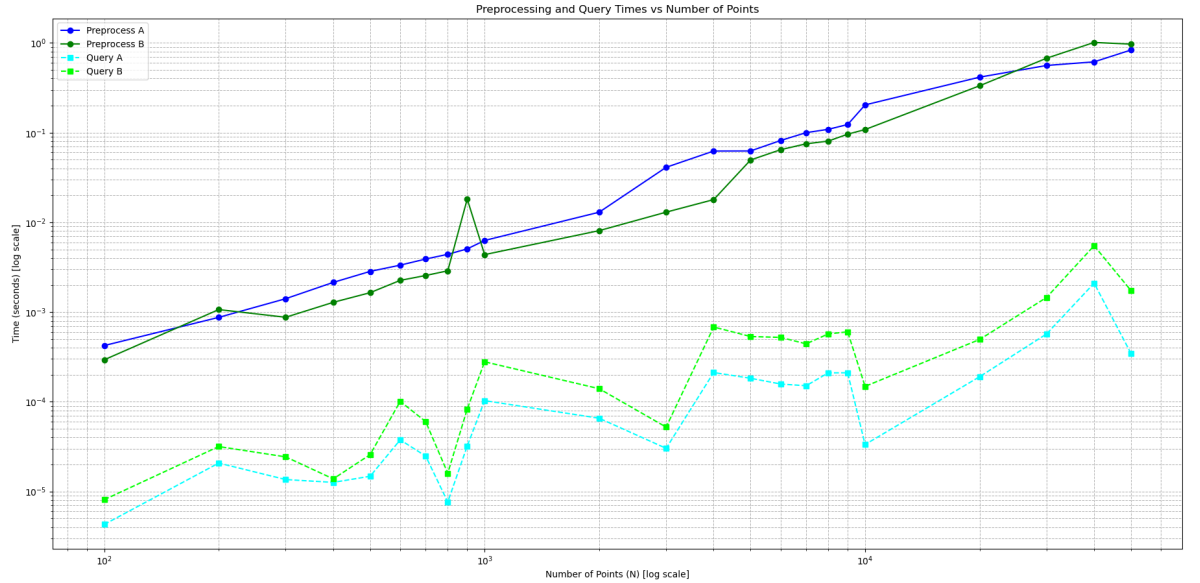

Figure 1: time comparison between standard 2D Range Tree and Fractional Cascading 2D Range Tree.

The plot generated has:

- **X-axis:** Number of points (n), in logarithmic scale.

- **Y-axis:** Time (seconds), also in logarithmic scale.
- **Curves:**
 - Preprocessing times of normal tree (A) and fractional cascading tree (B).
 - Query times of normal tree (A) and fractional cascading tree (B).

4.3 Observations

- Preprocessing times are similar for both methods, as both are $\mathcal{O}(n \log n)$.
- Query time for the fractional cascading approach is significantly better as n increases.
- Standard 2D Range Tree query grows as $\log^2 n$, while fractional cascading is closer to $\log n$.
- Experimental results validate theoretical expectations.

4.4 Conclusion

Applying fractional cascading greatly improves the query efficiency in range trees, especially for large datasets, while keeping preprocessing time and space costs manageable.
